

## Diferrous Structural and Functional Models of the Iron-only Hydrogenases

Christine A. Boyke

Final Seminar

April 12, 2006

The Fe-only hydrogenases catalyze the interconversion between protons and dihydrogen. The H<sub>2</sub>-binding center (H-cluster) in the Fe-only hydrogenases<sup>1-5</sup> adopts a face-shared bi-octahedral structure (Figure 1). The entire complement of ancillary ligands are unusual in the biological context.<sup>6</sup> Cyanide and CO are rarely observed in Nature, although they are also found in the NiFe hydrogenases.<sup>7</sup> Other unusual features include the dithiolate cofactor, the sulfur atoms of which bridge the iron atoms,<sup>5, 8</sup> and an Fe<sub>4</sub>S<sub>4</sub>(SCys)<sub>4</sub> cluster that is linked to the active site via a cysteinyl thiolate bridge. The oxidized, active form (H<sub>ox</sub>, see below) of the binuclear active site can be described as [Fe<sub>2</sub>[(SCH<sub>2</sub>)<sub>2</sub>X](CN)<sub>2</sub>(μ-CO)(CO)<sub>2</sub>(SR<sub>2</sub>)(L)]<sup>z</sup>, where SR<sub>2</sub> represents the thiolato-bridged Fe<sub>4</sub>S<sub>4</sub> ligand, X is speculated to be NH<sub>2</sub> and L is the H<sub>x</sub>-binding site (x = 1, 2) that can also be occupied by CO (H<sub>ox</sub><sup>CO</sup>) or possibly H<sub>2</sub>O.<sup>1, 9</sup>

**Figure 1.** Hydrogenase active site, H<sub>red</sub>(left) and [HF<sub>e2</sub>(S<sub>2</sub>C<sub>3</sub>H<sub>6</sub>)(CN)<sub>2</sub>(CO)<sub>4</sub>]<sup>-</sup> (right).

Oxidations of sub-ferrous compounds afford a new family of diferrous dithiolates. Low temperature oxidation of Fe<sub>2</sub>(S<sub>2</sub>C<sub>n</sub>H<sub>2n</sub>)(CNMe)<sub>6-x</sub>(CO)<sub>x</sub> (n = 2, 3; x = 2, 3) affords a family of mixed carbonyl-isocyanides of the type [Fe<sub>2</sub>(S<sub>2</sub>C<sub>n</sub>H<sub>2n</sub>)(CO)<sub>x</sub>(CNMe)<sub>7-x</sub>]<sup>2+</sup>.<sup>10</sup> The degree of substitution is controlled by the RNC/Fe ratio as well as the degree of initial substitution at iron, with tricarbonyl derivatives favoring more highly carbonylated products. The structures of the monocarbonyl derivatives [Fe<sub>2</sub>(S<sub>2</sub>C<sub>n</sub>H<sub>2n</sub>)(μ-CO)(CNMe)<sub>6</sub>](PF<sub>6</sub>)<sub>2</sub> (n = 2, 3) established crystallographically and spectroscopically, are quite similar, with Fe---Fe distances of ca. 2.5 Å, although the μ-CO is unsymmetrical in the propanedithiolate derivative. In the dicarbonyl species, [Fe<sub>2</sub>(S<sub>2</sub>C<sub>2</sub>H<sub>4</sub>)(μ-CO)(CO)(CNMe)<sub>5</sub>](PF<sub>6</sub>)<sub>2</sub>, the terminal CO ligand is situated at one of the basal sites, not trans to the Fe---Fe vector.

Oxidation of (Et<sub>4</sub>N)<sub>2</sub>[Fe<sub>2</sub>(S<sub>2</sub>C<sub>2</sub>H<sub>4</sub>)(CN)<sub>2</sub>(CO)<sub>4</sub>] in the presence of cyanide and tertiary phosphines and of Fe<sub>2</sub>(S<sub>2</sub>C<sub>2</sub>H<sub>4</sub>)(PMe<sub>3</sub>)<sub>2</sub>(CO)<sub>4</sub> in the presence of cyanide affords a series of diferrous cyanide derivatives (Scheme 1)<sup>11</sup> that bear a stoichiometric, structural, and electronic relationship to the H<sub>ox</sub><sup>air</sup> state of the Fe-only hydrogenases. With PPh<sub>3</sub> as the trapping ligand, we obtained an unsymmetrical isomer of Fe<sub>2</sub>(S<sub>2</sub>C<sub>2</sub>H<sub>4</sub>)(μ-CO)(CN)<sub>2</sub>(PPh<sub>3</sub>)<sub>2</sub>(CO)<sub>2</sub>, which was confirmed crystallographically. This diferrous cyanide features the *semibridging* CO ligand with

Fe- $\mu$ C bond lengths of 2.15 and 1.85 Å. Four isomers of  $\text{Fe}_2(\text{S}_2\text{C}_2\text{H}_4)(\mu\text{-CO})(\text{CN})_2(\text{PMe}_3)_2(\text{CO})_2$  were observed, the initial product again being unsymmetrical but more stable isomers are symmetrical. DFT calculations confirm that the most stable isomers of  $\text{Fe}_2(\text{S}_2\text{C}_2\text{H}_4)(\mu\text{-CO})(\text{CN})_2(\text{PMe}_3)_2(\text{CO})_2$  have cyanide trans to  $\mu\text{-CO}$ . Oxidative decarbonylation also afforded the new tetracyanide  $[\text{Fe}_2(\text{S}_2\text{C}_2\text{H}_4)(\mu\text{-CO})(\text{CN})_4(\text{CO})_2]^-$ . Insights into the oxidative decarbonylation mechanism of these syntheses comes from the spectroscopic characterization of the tetracarbonyl  $[\text{Fe}_2(\text{S}_2\text{C}_2\text{H}_4)(\mu\text{-CO})(\text{CN})_3(\text{CO})_3]^-$ . This species reacts with  $\text{PET}_3$  to produce the stable adduct  $[\text{Fe}_2(\text{S}_2\text{C}_2\text{H}_4)(\mu\text{-CO})(\text{CN})_3(\text{CO})_2(\text{PET}_3)]^-$ .

**Scheme 1.** Oxidative decarbonylation methodology for  $(\text{Et}_4\text{N})_2[\text{Fe}_2(\text{S}_2\text{C}_2\text{H}_4)(\text{CN})_2(\text{CO})_4]$ .

The protonation of  $(\text{Et}_4\text{N})_2[\text{Fe}_2(\text{S}_2\text{C}_3\text{H}_6)(\text{CN})_2(\text{CO})_4]$  has been further characterized. Low temperature IR spectroscopic studies show that the protonation of  $(\text{Et}_4\text{N})_2[\text{Fe}_2(\text{S}_2\text{C}_3\text{H}_6)(\text{CN})_2(\text{CO})_4]$  with HOTs gave  $\text{Et}_4\text{N}[\text{Fe}_2(\text{S}_2\text{C}_3\text{H}_6)(\text{CN})(\text{CNH})(\text{CO})_4]$ . The species,  $\text{Et}_4\text{N}[\text{Fe}_2(\text{S}_2\text{C}_3\text{H}_6)(\text{CN})(\text{CNH})(\text{CO})_4]$ , undergoes an approximate first-order decay to the hydride  $\text{Et}_4\text{N}[\text{HFe}_2(\text{S}_2\text{C}_3\text{H}_6)(\text{CN})_2(\text{CO})_4]$  (Figure 1). Addition of a second equiv of  $\text{H}^+$  to  $\text{Et}_4\text{N}[\text{HFe}_2(\text{S}_2\text{C}_3\text{H}_6)(\text{CN})_2(\text{CO})_4]$  resulted in protonation at the  $\text{CN}^-$  ligand to give  $[\text{HFe}_2(\text{S}_2\text{C}_3\text{H}_6)(\text{CN})(\text{CNH})(\text{CO})_4]$ .  $[\text{HFe}_2(\text{S}_2\text{C}_3\text{H}_6)(\text{CN})(\text{CNH})(\text{CO})_4]$  was shown to catalyze the reduction of protons at -1.5 V vs Ag/AgCl. Decarbonylation of  $\text{Et}_4\text{N}[\text{HFe}_2(\text{S}_2\text{C}_3\text{H}_6)(\text{CN})_2(\text{CO})_4]$  in the presence of  $\text{PPh}_3$  resulted in  $\text{Et}_4\text{N}[\text{HFe}_2(\text{S}_2\text{C}_3\text{H}_6)(\text{CN})_2(\text{CO})_3(\text{PPh}_3)]$  followed by  $\text{Et}_4\text{N}[\text{HFe}_2(\text{S}_2\text{C}_3\text{H}_6)(\text{CN})_2(\text{CO})_2(\text{PPh}_3)_2]$ , which exist as multiple isomers. MeCN solutions of  $\text{Et}_4\text{N}[\text{HFe}_2(\text{S}_2\text{C}_3\text{H}_6)(\text{CN})_2(\text{CO})_4]$  in the absence of  $\text{PPh}_3$  gave the solvolysis product,  $\text{Et}_4\text{N}[\text{HFe}_2(\text{S}_2\text{C}_3\text{H}_6)(\text{CN})_2(\text{MeCN})(\text{CO})_3]$  which reacts with  $\text{PMe}_3$  and  $\text{CN}^-$  to produce  $\text{Et}_4\text{N}[\text{HFe}_2(\text{S}_2\text{C}_3\text{H}_6)(\text{CN})_2(\text{PMe}_3)(\text{CO})_3]$  and  $(\text{Et}_4\text{N})_2[\text{HFe}_2(\text{S}_2\text{C}_3\text{H}_6)(\text{CN})_3(\text{CO})_3]$ , respectively.
